

WHAT IS CLAIMED IS:

1. A method for providing multi-channel functionality with a telecommunication device comprising a single channel, the method comprising:

- 5           dividing a scan chain of digital logic components into a plurality of sub-chains;  
            providing a first data set in the sub-chains;  
            linking the sub-chains in parallel;  
            linking the sub-chains to a device memory;  
10           executing a first application to update the first data set in the sub-chains, the first application operable to use the channel;  
            storing the updated first data set in the device memory;  
15           restoring a second data set from the device memory to the sub-chains; and  
            executing a second application to update the second data set in the sub-chains, the second application operable to use the channel.

- 20           2. The method of Claim 1, the device memory comprising a write port and a read port, storing the updated first data set in the device memory comprising shifting the updated first data set to the device memory  
25           through the write port, and restoring the second data set from the device memory to the sub-chains comprising shifting the second data set from the device memory through the read port to the sub-chains.

3. The method of Claim 1, the device operable to be placed in a test mode for testing, a functional mode for executing applications, and a switch mode for switching between applications, each digital logic  
5 component operable to receive test data over a test line and a test clock signal while the device is in the test mode, to receive functional data over a functional line and a functional clock signal while the device is in the functional mode, and to receive functional data over the  
10 test line and the functional clock signal while the device is in the switch mode.

4. The method of Claim 3, storing the updated first data set comprising storing the updated first data  
15 set while the device is in the switch mode, and restoring the second data set comprising restoring the second data set while the device is in the switch mode.

5. The method of Claim 1, further comprising:  
storing the updated second data set in the  
device memory;

restoring a third data set from the device  
5 memory to the sub-chains;

executing a third application to update the  
third data set in the sub-chains, the third application  
operable to use the channel;

10 storing the updated third data set in the  
device memory;

restoring a fourth data set from the device  
memory to the sub-chains;

15 executing a fourth application to update the  
fourth data set in the sub-chains, the fourth application  
operable to use the channel;

storing the updated fourth data set in the  
device memory; and

restoring the first data set from the device  
memory to the sub-chains.

20

6. The method of Claim 1, the device comprising  
one of an application-specific integrated circuit and a  
field-programmable gate array.

25 7. The method of Claim 1, each digital logic  
component comprising a flip-flop.

8. The method of Claim 1, dividing the scan chain  
of digital logic components into a plurality of sub-  
chains comprising dividing the scan chain into a  
specified number of sub-chains, the specified number  
5 corresponding to a data width for the device memory.

9. A method for providing multi-channel functionality with a telecommunication device comprising a single channel, the method comprising:

linking a plurality of sub-chains of digital  
5 logic components in parallel;

linking the sub-chains to a write port of a device memory and to a read port of the device memory;

providing a first data set in the sub-chains;

executing a first application to update the  
10 first data set in the sub-chains, the first application operable to use the channel;

shifting the updated first data set into the device memory through the write port;

shifting a second data set from the device  
15 memory through the read port into the sub-chains; and

executing a second application to update the second data set in the sub-chains, the second application operable to use the channel.

20 10. The method of Claim 9, the device operable to be placed in a test mode for testing, a functional mode for executing applications, and a switch mode for switching between applications, each digital logic component operable to receive test data over a test line  
25 and a test clock signal while the device is in the test mode, to receive functional data over a functional line and a functional clock signal while the device is in the functional mode, and to receive functional data over the test line and the functional clock signal while the  
30 device is in the switch mode.

11. The method of Claim 10, shifting the updated first data set into the device memory through the write port comprising shifting the updated first data set into the device memory while the device is in the switch mode, and shifting the second data set from the device memory through the read port into the sub-chains comprising shifting the second data set from the device memory while the device is in the switch mode.

10

12. The method of Claim 9, further comprising:  
shifting the updated second data set into the device memory through the write port;  
shifting a third data set from the device memory through the read port into the sub-chains;  
executing a third application to update the third data set in the sub-chains, the third application operable to use the channel;  
shifting the updated third data set into the device memory through the write port;  
shifting a fourth data set from the device memory through the read port into the sub-chains;  
executing a fourth application to update the fourth data set in the sub-chains, the fourth application operable to use the channel;  
shifting the updated fourth data set into the device memory through the write port;  
shifting the first data set from the device memory through the read port into the sub-chains.

30

13. The method of Claim 9, the device comprising one of an application-specific integrated circuit and a field-programmable gate array.

5        14. The method of Claim 9, each digital logic component comprising a flip-flop.

10        15. The method of Claim 9, dividing the scan chain of digital logic components into a plurality of sub-chains comprising dividing the scan chain into a specified number of sub-chains, the specified number corresponding to a data width for the device memory.

16. A telecommunication device comprising a single channel, the device comprising:

a scan chain comprising a plurality of digital logic components;

5 a device memory operable to store a data set for each of a plurality of applications; and

a state machine operable to divide the scan chain into a plurality of sub-chains, to provide a first data set in the sub-chains, to link the sub-chains in parallel, to link the sub-chains to the device memory, to execute a first application to update the first data set in the sub-chains, the first application operable to use the channel, to shift the updated first data set into the device memory for storage, to shift a second data set from the device memory into the sub-chains, and to execute a second application to update the second data set in the sub-chains, the second application operable to use the channel.

20 17. The device of Claim 16, each digital logic component comprising a flip-flop.

18. The device of Claim 16, the state machine further operable to divide the scan chain into a specified number of sub-chains, the specified number corresponding to a data width for the device memory.

19. The device of Claim 16, the state machine further operable to place the device in a test mode for testing, a functional mode for executing applications, and a switch mode for switching between applications,  
5 each digital logic component operable to receive test data over a test line and a test clock signal while the device is in the test mode, to receive functional data over a functional line and a functional clock signal while the device is in the functional mode, and to  
10 receive functional data over the test line and the functional clock signal while the device is in the switch mode.

20. The device of Claim 19, the state machine  
15 further operable to shift the updated first data set into the device memory while the device is in the switch mode, and to shift the second data set from the device memory into the sub-chains while the device is in the switch mode.

20
